

Time/Area Distribution and Composition of the Incidental Kill of Dolphins and Small Whales in the U.S. Purse-Seine Fishery for Tuna in the Eastern Tropical Pacific, 1979–80

W. F. Perrin and C. W. Oliver

Marine Mammal Biology Program, Southwest Fisheries Center, National Marine Fisheries Service, NOAA, La Jolla, California, USA 92038

ABSTRACT

Data are presented for 4,642 spotted dolphins, *Stenella attenuata*; 1,745 spinner dolphins, *S. longirostris*; 99 striped dolphins, *S. coeruleoalba*; 1,535 common dolphins, *Delphinus delphis*; two bottlenose dolphins, *Tursiops truncatus*; one Pacific white-sided dolphin, *Lagenorhynchus obliquidens*, and one false killer whale, *Pseudorca crassidens*. Possible source of biases in the samples are discussed.

INTRODUCTION

Data on composition of the U.S. incidental purse-seine kill of small cetaceans have been presented and analyzed in a series of publications (Perrin, Coe and Zweifel, 1976; Perrin, Holts and Miller, 1977; Perrin, Miller and Sloan, 1977; Perrin and Henderson, 1979; Smith, 1979; and Henderson, Perrin and Miller, 1980). Recent studies have shown that the data may be subject to biases, of several kinds. The purpose of this paper is to present the data for 1979 and 1980 and to discuss the biases affecting them.

METHODS

The kill data and the life-history specimens from which the data on reproductive condition were derived were collected by fishery technicians employed by the U.S. National Marine Fisheries Service (NMFS) and the Inter-American Tropical Tuna Commission (IATTC) aboard commercial purse-seiners. Data on kill by time and area reported here were collected only by the NMFS technicians. Data on sex composition, reproductive condition and length frequencies of the kill were collected by IATTC and NMFS technicians. NMFS technicians collected data on 62 cruises in 1979 and 41 cruises in 1980. IATTC technicians collected data on 25 cruises in 1979 and 38 in 1980. The sampling scheme is described in Smith (1979), and copies of the forms used are included here as Appendices 1 and 2. Laboratory procedures for processing the specimens and criteria for sexual maturity were as described in Perrin *et al.* (1975 and 1977). The management units used here are defined in Smith (1979). Dolphins not identified to species are not included in the data presented here. The NMFS observed-kill data are presented by 5°-square areas (Fig. 1). The computer programs used to summarize data on reproductive condition were described by Henderson and Perrin (1980).

RESULTS

Incidental kill data by area and month are presented for 8,026 small cetaceans in Tables 1–5. Sex data for 3,408

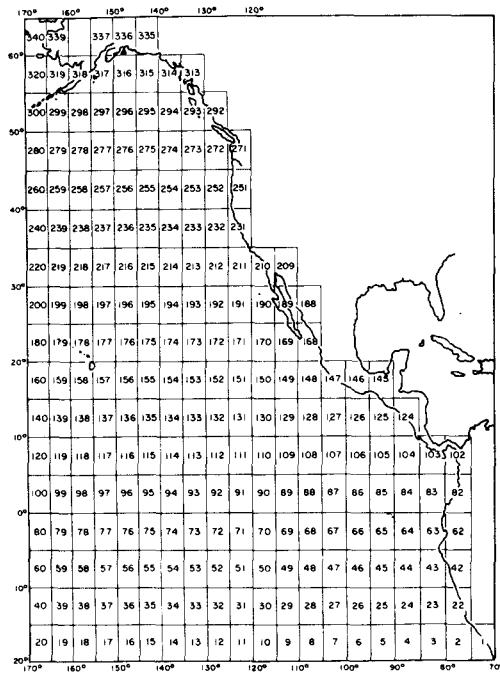

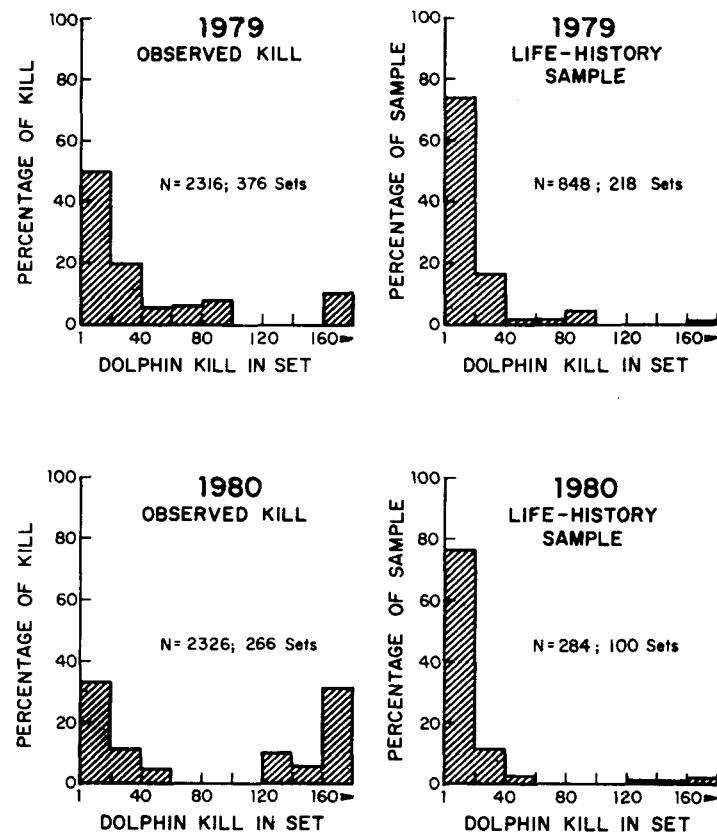

Fig. 1. Statistical reporting blocks (5-degree squares) for eastern tropical Pacific. Dashed line includes usual area of operation of US tropical-tuna purse-seine fishery (area of consideration for this paper). Solid line includes blocks in which data reported here were collected in 1979 and 1980.

dolphins, by area and quarter, are presented in Tables 6–10. Length-frequency data for 3,455 specimens are presented in Tables 11–13 and reproductive-condition data for 1,850 females in Tables 14–16. The tables can be found on pp. 000–00.

Fig. 2. Comparisons of kill-size structures of observed kills with those of subsamples from which life-history data and specimens were collected; for spotted dolphin, *Stenella attenuata*, in 1979 and 1980. Includes only data collected by NMFS technicians. The table compares kill-size structures of observed kill with those of subsamples for which life-history data and specimens were collected (same analysis as in Fig.); for spinner dolphin, *Stenella longirostris*; common dolphin, *Delphinus delphis*; and striped dolphin, *S. coeruleoalba*; 1979 and 1980 combined. Includes only data collected by NMFS observers.

DISCUSSION

Several potential sources of bias have been identified and are discussed below. For some, adjustment procedures have been developed; others have not yet been so addressed.

Effects of size of kill

Powers and Barlow (1979) examined the age structure of kill samples in relation to the size of the kill in the purse-seine set from which the samples came. They found that for the spotted dolphin, *Stenella attenuata*, samples from small-kill sets contained proportionately more calves than did those from large-kill sets. This has been interpreted to mean that calves are more vulnerable to death in the purse-seine operation than are adults, and therefore when only a few animals are killed, they tend to be calves. This would mean that the large-kill samples are more representative of the populations at large (or, at least, the animals captured) than are the small-kill samples. The most recent analyses of data for *S. attenuata* to estimate reproductive rates have taken this presumed effect into account by including only samples from net sets in which 40 or more spotted dolphins were killed (Henderson, Perrin and Miller, 1980). Powers and Barlow (1979) did not find a similar effect for the spinner dolphin, *S. longirostris*, and analyses for that species have been based on all samples regardless of kill size (Perrin and Henderson, 1979). The data for other species (*S. coeruleoalba* and *Delphinus delphis*) have not been examined for the presence of a kill-size effect.

An aspect of the kill-size effect that has not been taken into account relates to the fact that the technicians at sea do not process all dead animals that pass across the deck; they are limited to 30–40 dolphins by constraints of time and space. This means that the animals from small-kill (less than 30–40 sets) are usually all examined, whereas only a subsample of the animals from large-kill sets are examined, amplifying the bias caused by the kill-size effect for *S. attenuata* and possibly for *S. coeruleoalba* and *D. delphinus*. The under-representation of animals from large-kill sets in the life-history samples is shown in Fig. 2.

Effect of seasonality

Perrin *et al.* (1976) and Perrin *et al.* (1977) described diffuse seasonality in breeding of spotted and spinner dolphins in the eastern tropical Pacific, with two or more peak periods during the year. Because of the multiple peaks, the diffuseness, and the fact that the length of gestation is nearly a year (11.5 months in *S. attenuata* and 10.6 months in *S. longirostris*), the effect of seasonal sampling bias (as can be seen in Tables 1–5) on estimates of reproductive rates cannot be large. Barlow (1979) examined the effect of seasonality and developed a method to adjust for it. He found a maximum effect on pregnancy-rate estimates of 4% (for eastern spinner dolphins). Barlow also described variation in seasonal breeding peaks between sub-areas of what have been assumed to be areas containing single interbreeding populations. He concluded that the effect of seasonal-sampling bias on estimates of reproductive rates is probably more than the maximum 4% that he found because of this confounding of breeding units in the analyses. Stuntz (1980) also found areal variation in

seasonality, within putative interbreeding populations of the spotted dolphin. This confounding of populations, of course, has other implications for assessment and management. As fishing effort is not evenly distributed by area, the various cryptic subpopulations may differ from each other in status and production.

Other biasing effects

Stuntz (1980) found differences in the age structure of spotted dolphin samples with size of the dolphin school (more calves in smaller schools), tons of yellowfin tuna captured (fewer calves with larger tuna catches) and length of the chasing and coralling phase (see Perrin, 1969, for description of fishing operation) (fewer calves after longer chases) as well as with area and time of year. He pointed out that there are alternative explanations for the observed trends and noted that definitive analyses of the biases must be carried out before the structural (and reproductive) dynamics of the populations can be modeled with any confidence.

ACKNOWLEDGEMENTS

The owners, captains and crews of the U.S. tuna fleet cooperated fully with the collection of data and specimens. We thank them and the many NMFS and IATTC technicians who carried out the field work.

R. B. Miller and V. L. Cass processed the specimens in the laboratory and prepared the data for analysis. M. S. Lowry and T. C. Foster reviewed the final tables. K. S. Raymond prepared the figures, and V. Hostler typed the manuscript.
